DATE OF RELEASE: DECEMBER 29, 1975 - ATLANTA, GEORGIA 30333

EPIDEMIOLOGIC NOTES AND REPORTS
FATAL MUSHROOM POISONINGS - New York City

In October, 2 persons died in New York City following an illness compatible with poisoning from amatoxin-containing mushrooms.

Case 1

On October 16, 1975, a 37-year-old resident of Martha's Vineyard, Massachusetts, ate raw wild mushrooms which he had collected from his backyard. Within hours he experienced diarrhea, cramps, nausea, and vomiting; these symptoms persisted for 2 days. He also noted peripheral paresthesias and decreased mental acuity. On October 19, he was admitted to a hospital in Brooklyn, New York, with marked hepatic dys-

function. The next day he lapsed into hepatic coma and did not respond to charcoal hemoperfusion. At this point he was treated with thioctic acid without apparent effect. The remainder of his hospital course was further complicated by

MUSHROOM POISONINGS — Continued

renal insufficiency and massive gastrointestinal hemorrhage. He died on October 31. Necropsy revealed massive hepatic necrosis and acute tubular necrosis. Mushrooms picked from the backyard of the patient were identified as *Amanita phalloides*.

Case 2

On October 21, 1975, a 70-year-old resident of the Bronx, New York, cooked and ate wild mushrooms which he had collected from a park near the Whitestone Bridge in the Bronx. Ten hours later he experienced severe diarrhea, abdominal cramps, nausea, and vomiting. The following morning he was diagnosed as having gastroenteritis by an emergency room physician. Intravenous fluids and antispasmodics were administered, and he was discharged. The next day he was admitted to another hospital with hepatic and renal failure. Despite aggressive supportive therapy, he died 2 days later. Limited necropsy revealed areas of hepatic necrosis.

On November 14, the park where the mushrooms had been picked was explored; only a few mushrooms were found. These were speciated at the Bronx Botanical Park and determined not to be of the *Amanita* genus or other known genera of poisonous mushrooms.

(Reported by CT Rogerson, PhD, Bronx Botanical Gardens;

P Rhodes, MD, A Sutton, MD, Kings County Hospital Center; S Friedman, MD, R Katz, MD, JS Marr, MD, New York City Epidemiologist, Bur of Infectious Disease Control, New York City; Enteric Diseases Branch, Bacterial Diseases Div, Bur of Epidemiology, CDC.)

Editorial Note

These 2 patients had a clinical illness consistent with poisoning by mushroom species containing amatoxins; *A. phalloides* was probably the species responsible for case 1.

In 1974, 6 outbreaks of mushroom poisoning affecting 9 patients were reported to CDC. Two of these outbreaks were caused by *Galerina autumnalis* and *G. marginata*; these are members of the amanita toxin group which cause a serious illness with a relatively delayed onset. Other members of this group, *A. phalloides* (the death cap), *A. virosa* (the destroying angel), and *A. verna*, account for more than 95% of fatal mushroom poisonings worldwide.

Thiocotic acid, widely used in Europe for mushroom poisoning, is available in the United States as an experimental drug. It may be obtained from the National Institutes of Health, Bethesda, Maryland by contacting Dr. Frederick Barker or Dr. Jerry Mitchell (301-496-1518 weekdays, 301-656-4000 or 202-244-5562 nights and weekends).

CURRENT TRENDS

PRIMARY AND SECONDARY SYPHILIS — United States, October 1975

The 2,342 primary and secondary syphilis cases reported in October 1975 were 2.5% more than the 2,285 cases reported in October 1974. During the first 10 months (January-October) of 1975, such cases totaled 21,581, re-

resenting an increase of 1.3% over the number reported in the same time period of the previous year.

(Reported by the Venereal Disease Control Div, Bur of State Services, CDC.)

†Delayed Report for Week Ending December 20, 1975

INFLUENZA - Trust Territory and Hawaii

A/Victoria/3/75(H3N2)-like strains of influenza virus have been reported in association with outbreaks of influenza in the Trust Territory of the Pacific Islands and in Hawaii.

Kwajalein Atoll-Kwajalein Missile Range, Trust Territory of the Pacific Islands

Between October 11-November 1, an outbreak of acute febrile upper respiratory disease occurred among the residents on Kwajalein Missile Range in the Trust Territory of the Pacific Islands. A similar outbreak had recently occurred among the Marshallese population on the neighboring island of Ebeye.

Investigation revealed a clinical attack rate of 30% among the population of 3,400 with cases clustered in families and evenly distributed among adults and children. Serologic studies indicated that an influenza A virus was the cause of the outbreak.

A/Victoria-like strains were isolated from 2 asymptomatic individuals from Kwajalein passing through Hawaii during the time of the outbreak.

Hawaii

During October, 5 isolates of influenza B were reported from Hawaii. The specimens were submitted by private practitioners and were obtained from sporadic cases. Isolates

have been characterized as similar to the B/Hong Kong/5/72 strain.

In November, an outbreak of influenza occurred in a private elementary/secondary school in Honolulu. During the outbreak approximately 200 students out of 2,600 enrolled were seen in the dispensary for influenza-like illness. A total of 41 of the 611 boarding students were hospitalized in the infirmary during the course of the outbreak. Primary findings in those ill were fever, sore throat, and cough. Of 12 throat swabs taken from November 14-21, 1 isolate of an A/Victoria-like strain was obtained from a 9th grade boy and 4 isolates of influenza B were obtained from other students.

Another isolation of an A/Victoria-like strain of influenza A was obtained from a 4th grade boy attending a public elementary school on the outskirts of Honolulu. He was cultured in mid-November during a small outbreak of febrile upper respiratory illness in that school.

(Reported by G Kobayashi, A Oda, and NH Wiebenga, MD, State Epidemiologist, State Dept of Health, Honolulu, Hawaii; J Beal, MD, O Currid, and R Sullivan, Kwajalein Missile Range; FT Palacios, MD, Territorial Epidemiologist, Saipan, Trust Territory of the Pacific Islands; Respiratory Virology Branch, Virology Div, Bur of Laboratories, and Field Services Div, Bur of Epidemiology, CDC.)

**EPIDEMIOLOGIC NOTES AND REPORTS
DEATHS AT A RENDERING PLANT - Ohio**

On June 30, 1975, 6 men died of asphyxiation at an animal waste products rendering plant in Franklin County (Columbus), Ohio. In response to a request from the Occupational Safety and Health Administration (OSHA), the National Institute of Occupational Safety and Health began an investigation of the operations of the plant.

The animal waste products at this plant are delivered by truck, weighed, and dumped into a subterranean holding pit. After the trucks are unloaded, they are washed out with the drainage entering a pit below the scales (pit 1). This pit normally drains into an adjoining pit (pit 2) by gravity through a 6-inch drain pipe. Before this accident, however, the drain pipe had been clogged for between 2-7 days.

On June 30, a maintenance man descended into pit 2 to open the clogged drain and spent approximately 20 minutes in the pit with no apparent ill effects. After unclogging the drain, he immediately returned to the surface. Later he reentered the pit to shut off a sump pump, but collapsed while attempting to climb out of the pit. Assuming that the man had slipped and fallen, 3 men went to aid him; they, too, collapsed unconscious.

A 2-man rescue squad then arrived; believing the problem to be an electrical one, they entered pit 2 to attempt rescue. Almost immediately, they also fell to the pit floor unconscious. Additional help was sought from fire department rescuers, who removed the 6 men from the pit using self-contained air packs. Many of these and subsequent rescuers became symptomatic during the rescue operations; 6 were hospitalized with dizziness, faintness, shortness of breath, chest heaviness, coughing, choking, nausea, and vomiting. Four of the 6 fallen men were dead when removed from the pit; 1 was dead on arrival at the hospital; and 1 died at the hospital 4 days later, without having regained consciousness.

Postmortem findings showed cause of death in all of the men to be general anoxia with acute edema of the brain and lungs. Four had evidence of severe respiratory irritation; 1 showed greenish discoloration of the viscera — a finding associated with hydrogen sulfide poisoning. Blood from the deceased workers was negative for cyanomethemoglobin, and carboxyhemoglobin did not exceed normal ranges. Methane was found in the blood of 5 patients and sulfmethemoglobin levels were negative, consistent with sulfide poisoning. Coins and keys carried by the patients were deeply darkened, indicating the formation of metallic sulfides.

Present medical and environmental evidence suggests that hydrogen sulfide alone or in combination with methane and carbon dioxide was the most likely cause of the accident. The clogging of the drainpipe may have permitted organic material to accumulate in the scale pit where it underwent anaerobic and aerobic decomposition, producing gases such as hydrogen sulfide, carbon dioxide, or vapors of organic acids (1). Investigations are continuing in an attempt to determine which of these gases or what combination was primarily responsible for the illnesses and deaths.

(Reported by W Adrián, MD, Franklin County Coroner; J Bernans, ME Olney, RC Temple, Lt, Franklin Township Fire Dept; M Fulmer, R Kimmerer, JH Oliver, Columbus area office, OSHA; D Selchar, E Tyler, Ohio State Div of Safety and Hygiene; G Shadie, MD, TJ Halpin, MD, State Epidemiologist, Ohio State Dept of Health; M Gohar, Ohio State Arson Laboratory; and Div of Technical Services NIOSH, CDC.)

Editorial Note

Toxic gases can accumulate where organic substances have the opportunity to decay in a confined space. Hydrogen sulfide (H_2S), the most powerful of these gases, can evolve whenever the decaying organic materials contain sulfur.

DEATHS AT A RENDERING PLANT - Continued

Deaths from such exposure have been reported among gypsum, sulfur, and lead miners, drillers, and refiners of high-sulfur petroleum; sewer cleaners; and, as apparently happened here, among tanners and animal rendering plant workers (2). Testing for a "rotten egg" smell is not sufficient safeguard against such exposure, as H₂S can rapidly induce olfactory nerve paralysis. Adequate ventilation should be provided, but if ventilation is not possible, the space to be entered should be vented, and proper air sampling undertaken before entry. If this cannot be done, the entering worker should be provided with an air-supplied respirator and a safety harness and line to make rapid removal possible.

In addition, another person similarly equipped should stand by outside the confined space.

Anne D. Mather, M.A.

The data in this report are provisional, based on weekly telegraphs to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

In addition to the established procedures for reporting morbidity and mortality, the editor welcomes accounts of interesting cases, outbreaks, environmental hazards, or other public health problems of current interest to health officials.
